Hospital Royal Vinohrady

Electroporation

= formation of **pores** in the **cell membrane** by **short high-voltage pulses**

According to the **electric field setting, length and number of pulses**

Reversible

- **temporary** increase in cell membrane permeability through pores
- **transport of large molecules** (DNA, RNA, chemotherapeutics) → **gene transfection**

Irreversible

- **permanent** increase in cell membrane permeability
- induction of cell **death**

What happens:

Threshold $E \sim$ (500–1000 V/cm)

Irreversible electroporation in arythmology

=

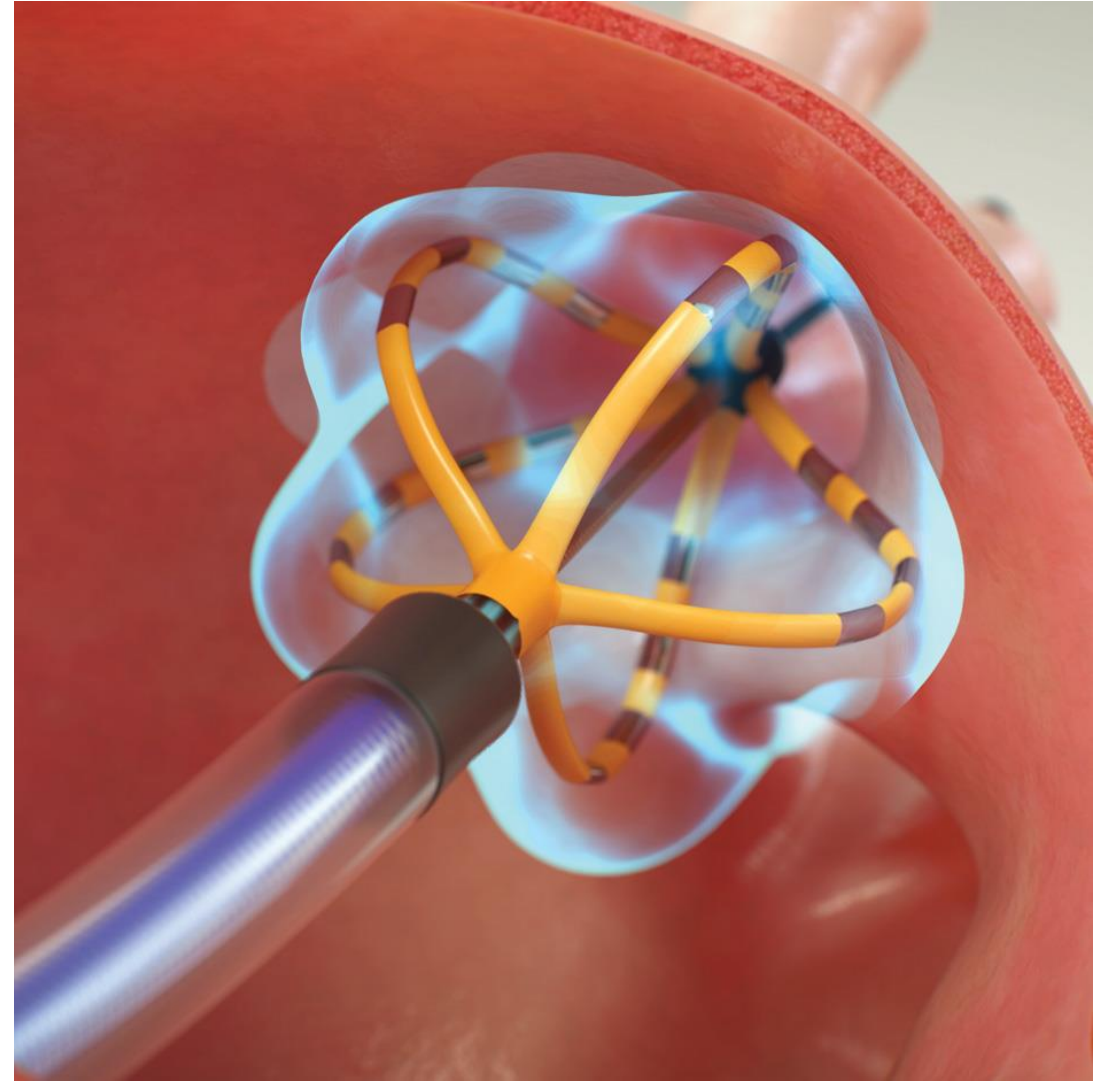

PULSED FIELD ABLATION

- Cathetrisation therapy for atrial fibrillation
- More **effective and faster** (compare to RF ablation)

Our scientific
Questions???

Threshold for irreversible
electroporation of
cardiomyocytes

Heamolysis
induction

FARAPULSE - catheter for the treatment of atri

Methods

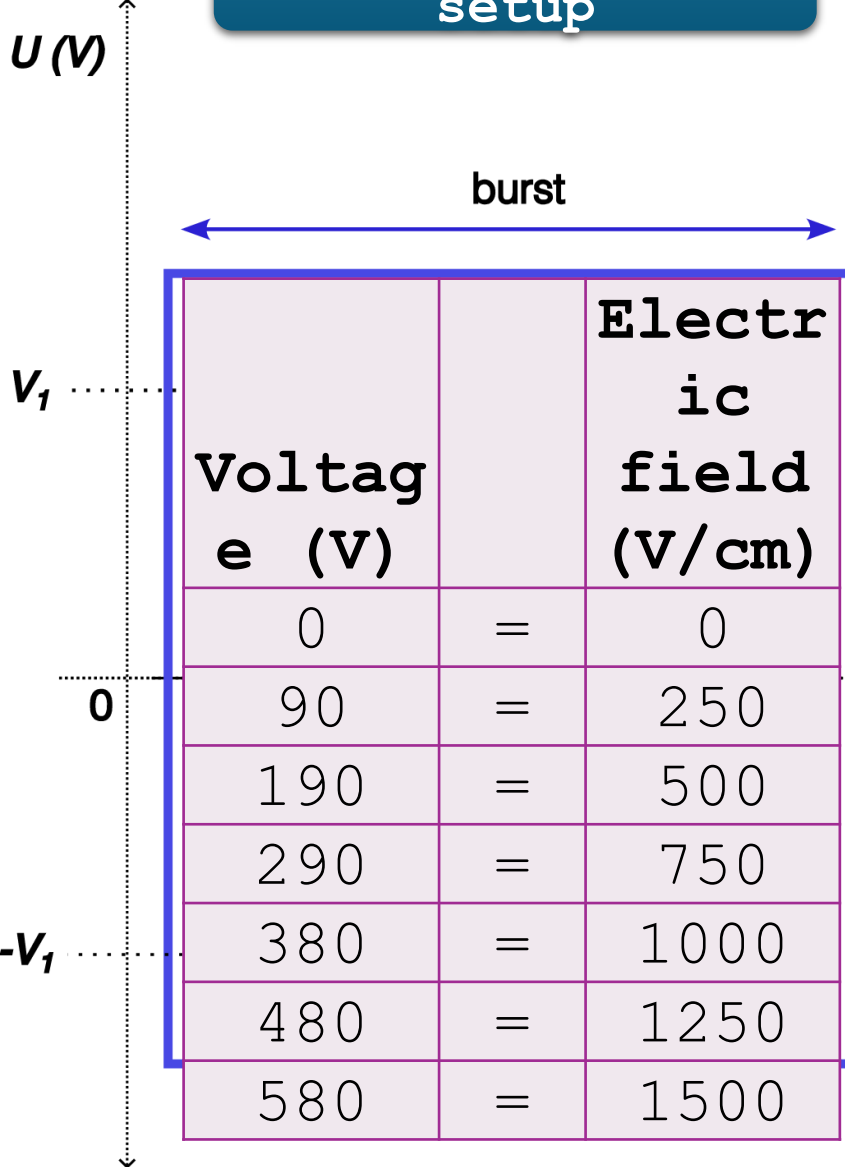

Threshold for irreversible electroporation of cardiomyocytes

Cell model

- immortalized mouse atrial cardiomyocyte tumor line (HL-1)

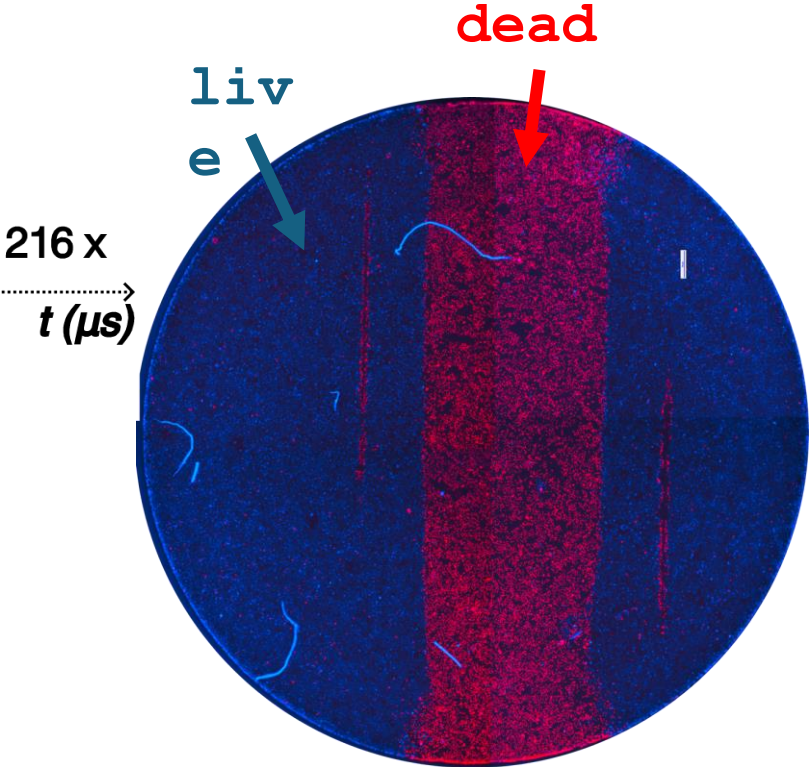

Electroporation setup

Detection of cell death

- Fluorescence microscopy
- 1 hour, 24 hours

Methods

Heamolysis induction

Blood samples

- Collection of blood from 12 healthy volunteers

Electroporation setup

- Same as cardiomyocytes

Detection of heamolysis

- Colorimetric detection of free heamoglobin

$$Hb \left(\frac{g}{l} \right) = \frac{k * (167.2 * A_{415} - 83.6 * A_{380} - 83.6 * A_{450})}{1000}$$

$K =$
dillution
 $A =$
absorbance

Temperature

Heat transfer in
solids and
fluids
Events
Laminar flow

Electrical conductivity of tissue

- Dependent on frequency and applied electric field (permeabilization)

$$\sigma(E) = \frac{\sigma_0 + (\sigma_1 - \sigma_0)}{1 + 10 \cdot e^{\frac{E(i) \cdot 100 - A}{B}}}$$

$$A = \frac{E_0 + E_1}{2}$$

$$B = \frac{E_1 - E_0}{2}$$

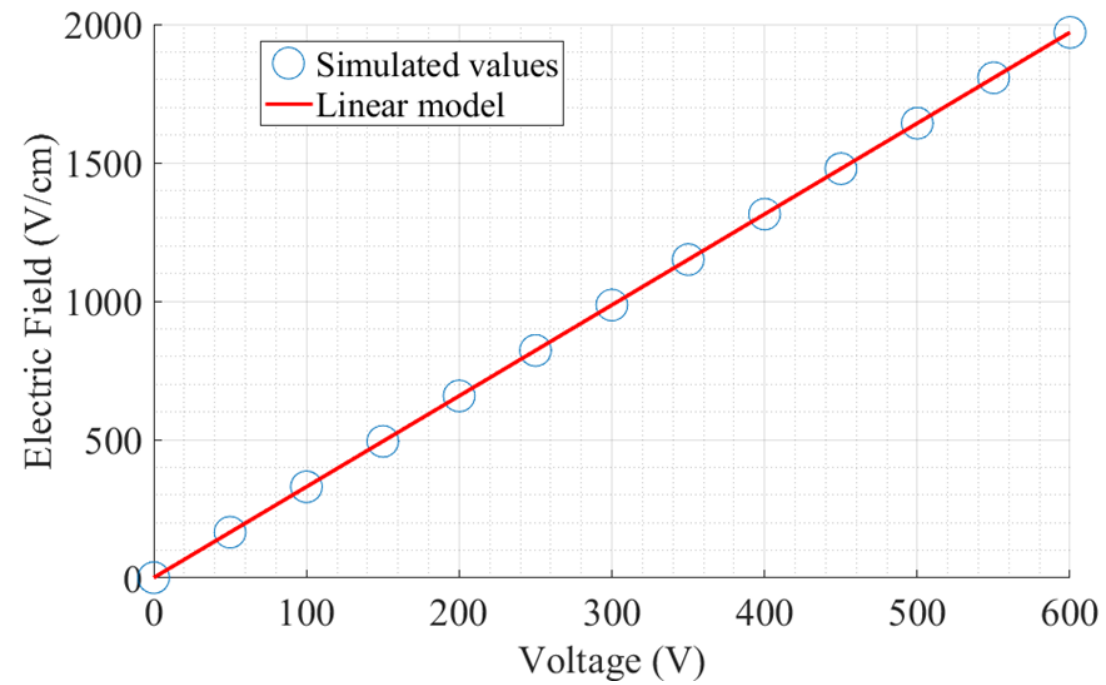

Parameter	Value
σ_0	0.067 (S/m)
σ_1	0.241 (S/m)

Temperature measurement

- Miniature negative temperature coefficient (NTC) temperature sensor
- Measurement frequency 100 Hz

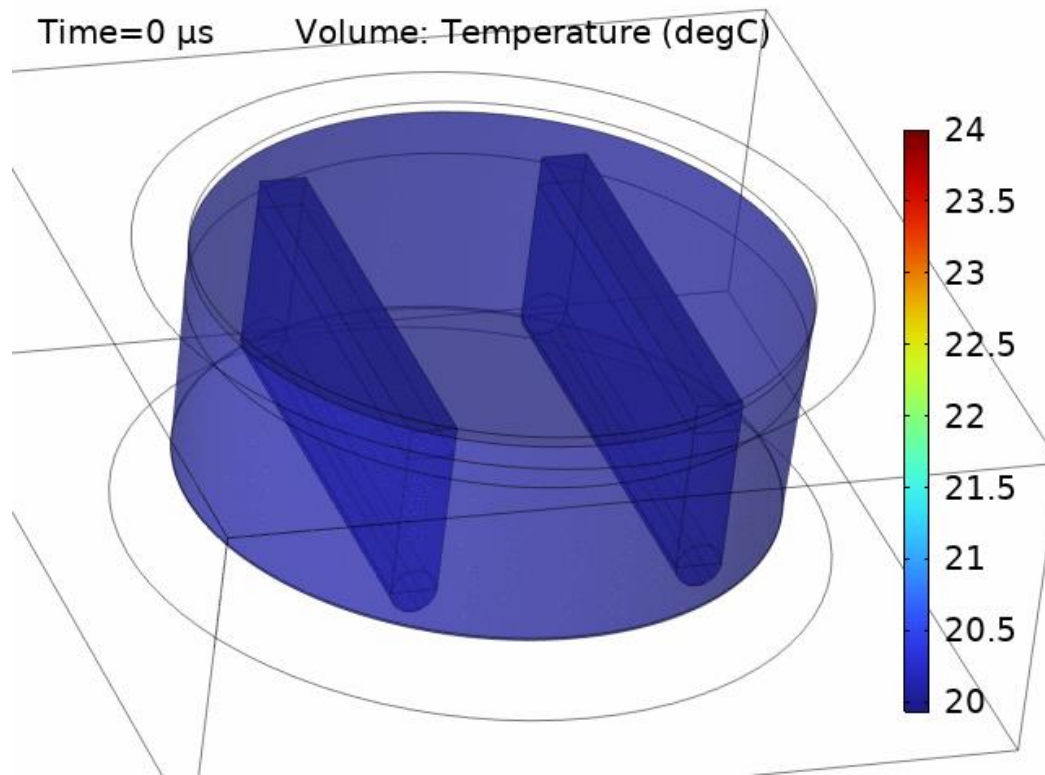

Results

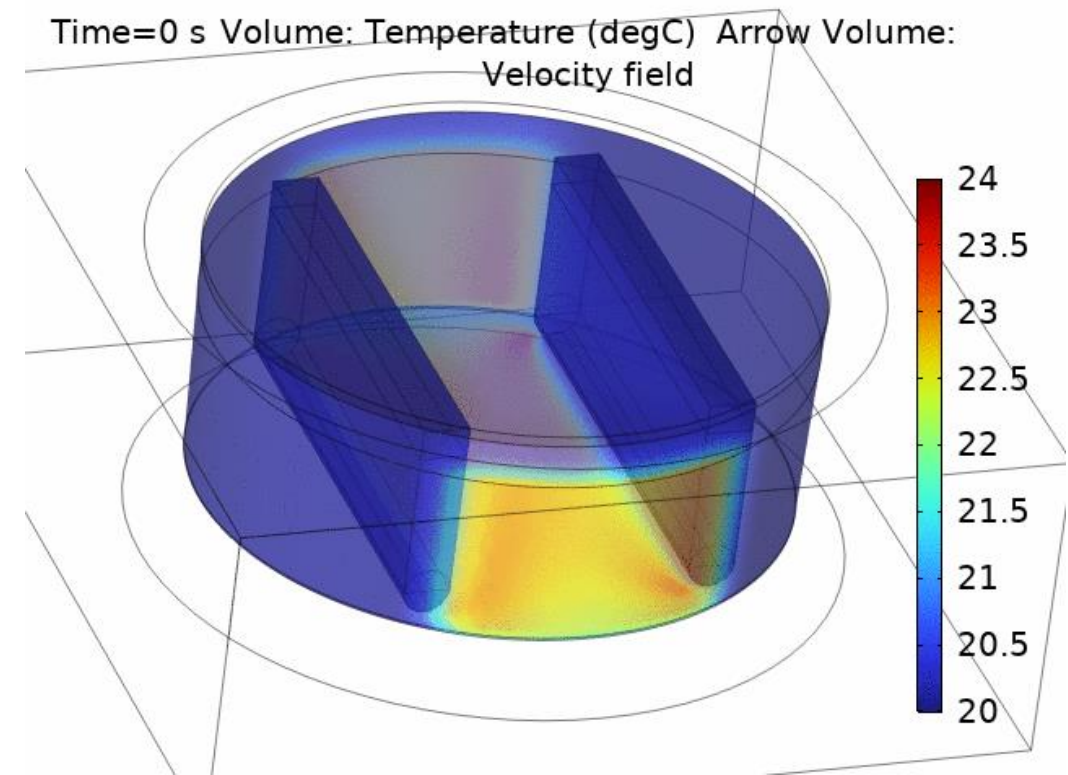

Results

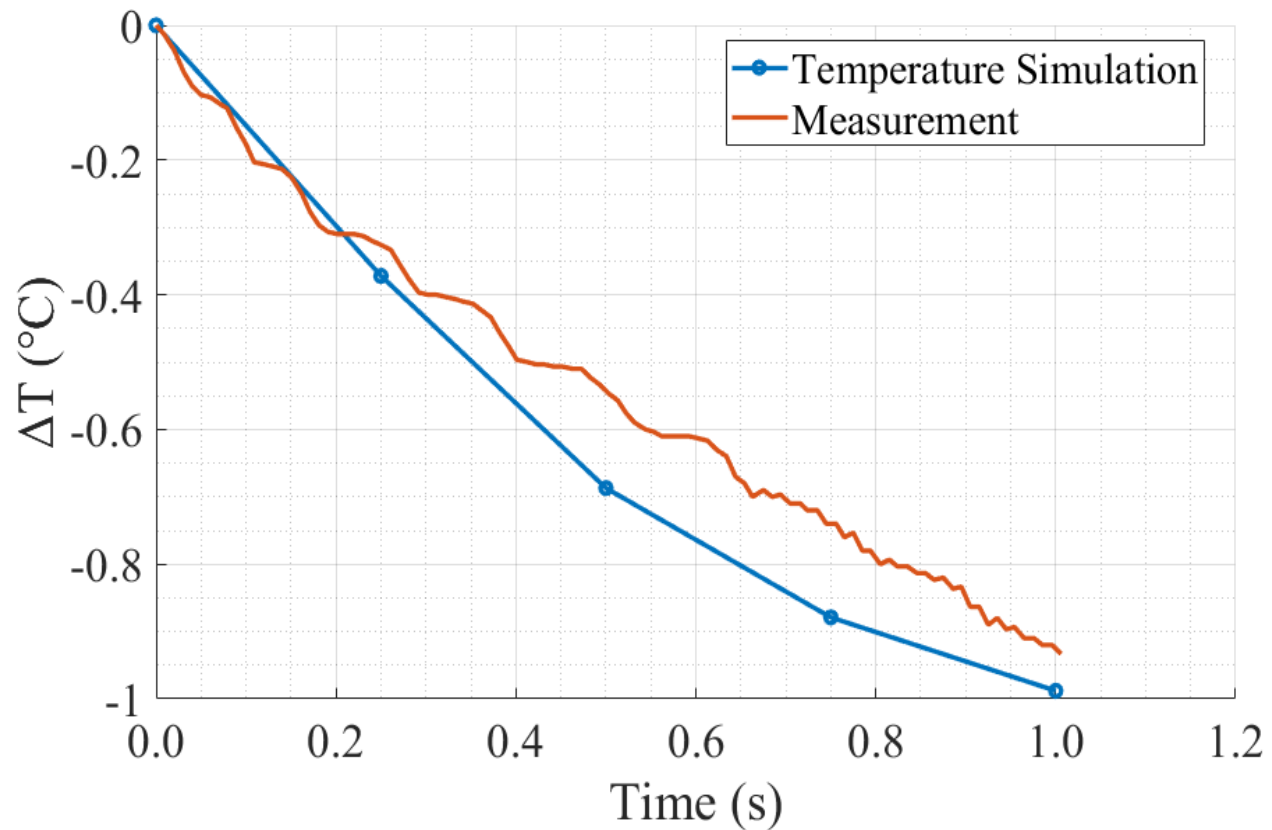

- Application of pulses

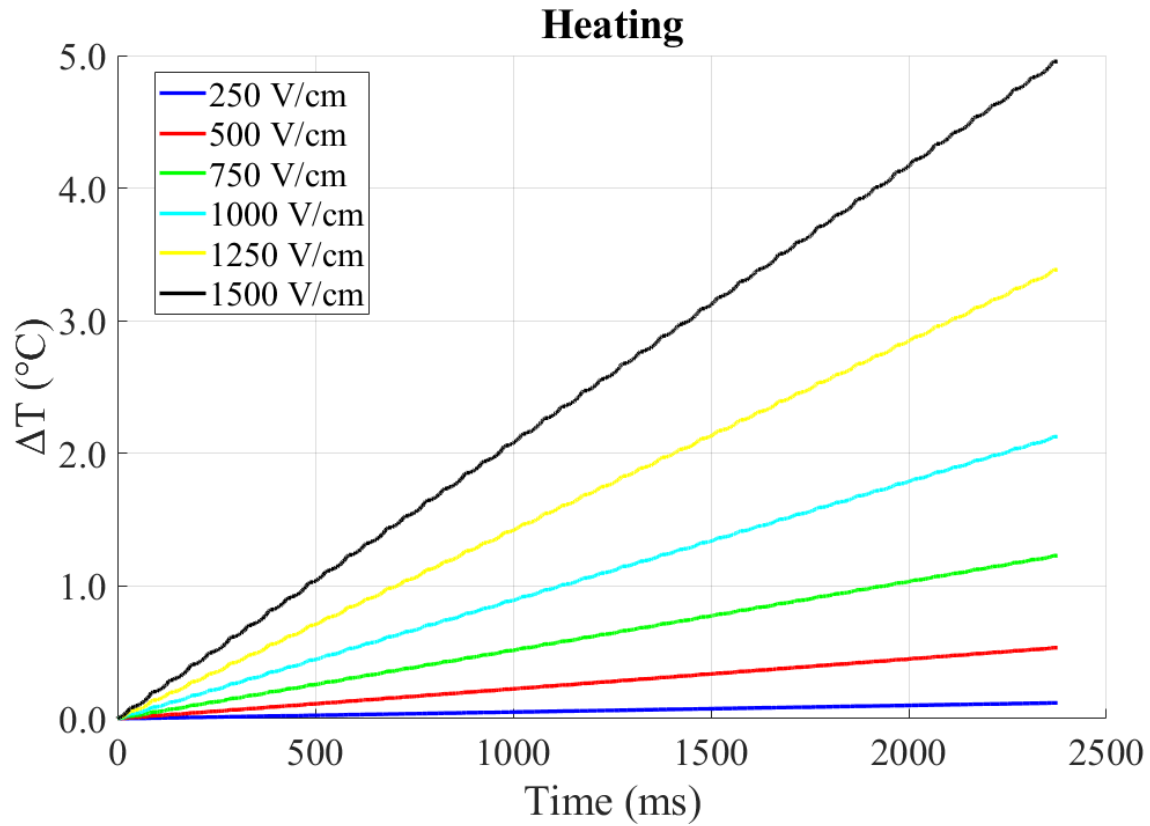

- Cooling
